

- You are given a permutation $(a_i)_{1 \leq i \leq n}$ of the numbers 1 to $n \leq 5 \cdot 10^5$.
- You want to turn it into a “mountain-shaped” permutation $(b_i)_{1 \leq i \leq n}$, meaning it is first increasing and then decreasing.
- You want to keep as many indices of the permutation the same, so maximize the number of i such that $a_i = b_i$.
- What is the smallest number of indices that need to change?

Illustration of Sample 1, where it's optimal to swap the first and last element.
The answer is therefore 2.
